Abstract

A field experiment was conducted at the Instructional Farm of UBKV during rabi seasons of 2008 and 2009 to assess intercropping effect in okra with an objective to generate more income from the farm through increased cropping intensity and complete and economical use of natural resources by combining nine different treatment combinations of different intercrops like cowpea, amaranthus, radish and palak in 1:1 row ratio. The trial was laid out in randomized block design (RBD) with four replications. Experimental results indicated that sole cropping of okra recorded significantly maximum values for most of the vegetative parameters. Sole cropping of okra recorded maximum number of marketable fruits plot-1 (1502.81), maximum fruit weight (17.11 g) and highest yield ha-1 (11.54 t). However, maximum okra equivalent yield ha-1 (15.67 t) was observed in okra+cowpea intercropping system. Minimum value for the same (9.02 t ha-1) was recorded in okra+radish intercropping system.

The study revealed that ascorbic acid content of the okra fruit was not significantly affected due to intercropping. Okra+cowpea intercropping system was found best user of biological resources as it recorded maximum values for LER (1.56), RCC (13.75) and lower values of aggressivity (-0.14) and competitive ratio (0.93). Economic analysis also showed that okra+cowpea intercropping system was most remunerative as it recorded highest net return and B:C ratio (₹ 1,35,891.50 and 2.61, respectively). Based on the findings, growing of cowpea with okra may be adjudged as the best intercrop for sustainable vegetable production.

1. Introduction

India is the second largest producer of vegetable in the world after China. In 2012–13 India produced 162.90 mt of vegetables from 9.40 mha area with a productivity of 17.30 t ha-1 in which West Bengal alone supplied 23.05 mt which was nearly 20 percentage of the country’s total vegetable production (NHB 2013–14). West Bengal is ideally suitable for cultivation of different vegetable crops. Among different vegetables grown, okra is a promising vegetable for the farmers of West Bengal. But the productivity of this crop is lower compared to national average. In India okra is popularly grown in mixtures with staple food crops such as yam, maize, cassava, cowpea and pepper or with various vegetable crops on small farm holdings (Odeleye et al., 2005). Among different plant production tools, intercropping of compatible crops can be of great value in achieving the improved productivity without requiring significant additional resources. The peasant farmers generally prefer the intercropping system because it produces higher total crop yield unit-1 area, provides insurance against total crop failure, and also reduces incidences of pests and diseases (Lyocks et al., 2013). The advantages of intercropping are risk minimization, effective use of available resources, efficient use of labour, increased crop productivity, erosion control and food security (Addo-Quaye et al., 2011). Yield advantage occurs because growth resources such as light, water, and nutrients are more completely absorbed and converted to crop biomass by the intercrop over time and space as a result of differences in competitive ability for growth resources between the component crops, which exploit the variation of the mixed crops in characteristics such as rates of canopy development, final canopy size (width and height), photosynthetic adaptation of canopies to irradiance conditions, and rooting depth. Careful planning is required when selecting the component crops of a mixture, taking into account the environmental conditions of an area and the available crops or varieties. It was shown by many researchers that intercropping of different vegetable crops provided important advantages as well as higher profitability than vegetables grown as sole crops (Nursima, 2009).
Moreover, because inorganic fertilizers have contributed to environmental damage such as nitrate pollution, legumes grown in intercropping are regarded as an alternative and sustainable way of introducing N into lower input agro-ecosystems (Fustec et al., 2010). Keeping all these facts in mind, the present study has been undertaken to assess the influence of intercropping in okra for sustainable vegetable production.

2. Materials and Methods

The present experiment was carried out during rabi seasons of 2008 and 2009 at the instructional farm of Uttar Banga Krishi Viswavidyalaya, Pundibari, Cooch Behar, West Bengal. The climatic condition of characterized by high rainfall (250–300 cm annum\(^{-1}\)), high relative humidity (80–85\%), moderate temperature (25–30 °C) prolonged winter with high residual soil moisture. The treatments included \(T_1\): Sole okra (control); \(T_2\): Sole cowpea; \(T_3\): Sole amaranthus; \(T_4\): Sole radish; \(T_5\): Sole palak; \(T_6\): Okra+cowpea; \(T_7\): Okra+amaranthus; \(T_8\): Okra+radish; \(T_9\): Okra+palak. The treatments were laid out in randomized block design with four replications. The variety used for okra was Arka Anamika. Recommended package of practices were followed for sole okra and sole intercrops. Seeds of intercrops were sown in between the rows of okra, spaced at 50×50 cm\(^2\). In intercropping situations, all the intercrops received the package of practices as in case of the main crop, okra. Ascorbic acid content of fruit was determined by the procedure given by Ranganna, (1986) and was expressed in mg 100 g\(^{-1}\). The observations recorded from different treatments in the field for okra were subjected to statistical analysis by adopting the Randomized Block Design (RBD) method suggested by Panse and Sukhatme (2000).

3. Results and Discussion

3.1. Growth parameters

The pooled result, pertaining to growth characters, presented in Table 1, indicated that most of the growth attributes were significantly influenced due to intercropping. Sole cropping of okra recorded significantly maximum values for most of the growth characters like plant height (98 cm), leaf number (23.67) and root length (10.65 cm). On the other hand, okra+cowpea intercropping system also higher values for shoot weight (509.03 g), root weight (23.70 g), and root volume (34.18 cc). Highest shoot to root ratio was recorded in okra+radish intercropping system (28.53). After sole cropping of okra, okra+cowpea system of intercropping has recorded higher values for most of the growth characters which might be due to better utilization of resources as there was lesser competition from the component crops for solar radiation, increasing plant height, leaf numbers, etc. compared to other intercropping treatments. This result is in conformity with the findings of (Sharma et al., 2009) in pearl millet based intercropping system.

</table>
Okra fruit was not significantly affected due to intercropping. Maximum value of ascorbic acid content of okra fruit was observed in okra+cowpea intercropping system (25.28 mg 100 g⁻¹) which was only statistically at par with that of sole okra (24.27 mg 100 g⁻¹) but significantly superior to all other treatment combinations.

3.3. Competitive functions

Regarding competitive functions, presented in Table 2 okra+cowpea intercropping system was found best user of biological resources as it recorded maximum values for LER (1.56), RCC (13.75) and lower values of aggressivity (-0.14). Similar type of results were also obtained by Hugar and Palled (2008) in maize+French bean intercropping system, John and Mini (2005) in okra+cowpea intercropping system and Seran and Brintha (2009) in capsicum+vegetable cowpea intercropping model.

3.4. Economics

Economic analysis, presented in Table 2, showed that okra+cowpea intercropping system was most remunerative as it recorded highest net return and B:C ratio (` 1,35,891.50 and 2.61 respectively). This result was in conformity with the findings of (Matusso et al., 2014) who found that among different intercropping combinations maize+soybean intercropping model were most remunerative with highest net return and maximum B:C ratio values.

4. Conclusion

Intercropping in okra was found promising than its sole cropping. Among different treatments growing of cowpea with okra in 1:1 proportion was found best for maximum okra equivalent yield, greater monetary benefit, highest production efficiency and higher ascorbic acid content of the fruits as this system of intercropping was efficient user of biological resources. Intercropping radish with okra was least remunerative and recorded minimum values for most of the vegetative, reproductive and quality parameters.
